Uninstall Nexus Repository On Ubuntu

To uninstall Nexus Repository and remove all related resources, including data, you can follow these steps:

Step 1: Uninstall the Nexus Helm release

Use the `helm uninstall` command to remove the release and all associated resources in the `nexus` namespace.

```
helm uninstall nexus --namespace nexus
```

* This will remove the Nexus Repository release, but any persistent data (e.g., volumes, secrets) might still remain in your Kubernetes cluster *

Step 2: Delete the Nexus namespace (optional)

If you want to completely remove the Nexus namespace and all resources within it (including persistent volumes, secrets, and config maps), you can delete the entire namespace:

```
kubectl delete namespace nexus
```

* This will ensure that all Kubernetes resources created under the nexus namespace are deleted, including any persistent storage (e.g., volumes) that may not have been removed by Helm *

Step 3: Delete persistent volumes (if necessary)

If you created persistent volumes manually or if Helm didn't clean up some of the volumes, you can remove them manually:

List the persistent volumes:

```
kubectl get pv
```

Delete the persistent volume(s) associated with Nexus (make sure they are no longer in use):

```
kubectrl delete pv <pv-name>
```

Step 4: Clean up any remaining secrets (optional)

You can delete the Nexus-related secrets manually as well:

```
kubectrl delete secret --namespace nexus nexus-repository-manager-admin-password
```

** Once you have done all these steps , Nexus should be completely removed from your Kubernetes environment **
